

React Native Support

Last Updated: Monday, June 15, 2020

Currently, Vibes does not have a React Native wrapper. Support can be easily implemented at a native level.

The following sample apps provide example code on how to implement the SDK in React Native:

- React Native .60: <https://github.com/vibes/react-native-sample-060>
- React Native .5X: <https://github.com/vibes/react-native-sample>

Key Integration Steps

- Implement basic device and push registration to simple push notifications.
- Enable [association of push to device](#) API or SDK call. This will make a user "known" and allow for platform targeting and segmentation. Note: If you are using cross channel segmentation between channels, the *external_person_id* must be the same in the SMS, Push, and Wallet channels.
- Add advanced push options: rich push, notification sounds, deep linking, etc (Optional)
 - Rich Push on iOS requires additional steps for implementation. Reference the [Rich Push](#) section of the [sample app](#) for detailed instructions.
- Add app inbox support (Optional)

Note: Platform accounts are available via the platform for development and UAT testing.
